

# Demo Script: DevCon 2024

- I have 25 minutes for the demo portion:
  - 0:01: Download and open twinBASIC

## Download and Save Sample Code

1. Download [twinBASIC BETA 504](#)
2. Extract from Zip folder
3. Open twinBASIC > **Sample 4**
4. Enter Project Name: Demo2024 (*Do not put spaces in the name*)
5. Save as: %tmp%\Demo2024\Demo2024.twinproj
  1. Navigate to: %tmp%
  2. Create folder named: Demo2024
  3. Filename: Demo2024.twinproj

## Customize the Addin Name and Description

Next, let's customize the friendly name and description of our addin. This is the info that appears in the VBA Add-in Manager dialog box.

1. Go to **dllRegistration.twin > DllRegisterServer**
2. In the "FriendlyName" line, replace *AddinProjectName* with "DevCon 2024 Demo"
3. In the "Description" line, replace *AddinProjectName* with "Create a strongly-typed collection class from an existing VBA class object."
4. Save the project
5. Build the project
6. Launch M:\Repos\NLS\DevCon2024\DevCon2024.accdb
7. Switch to VBA: **Ctrl** + **G**
8. Dock the add-in window
9. Go to "Add-Ins" > "Toggle myToolWindow Visibility"
10. Go to "Add-Ins" > "Add-in Manager"
  - Point out the "DevCon 2024 Demo" item with description below
11. Close "Add-In Manager" window

## Create the Tool Window Controls

Next, we're going to customize the controls that appear on the tool window. I'll explain what these controls will be used for in a minute. For now, all you need to know is that we are adding two text boxes, a command button, and a label to hold a version number.

1. Open myToolWindow.tbcontrol
2. Select all controls and delete them
3. Click DIAGNOSTICS error to go to myToolWindow.twin and **delete all dead code**
4. Select form and set the following properties:
  - Height: 1700
  - Width: 2550
5. Create a text box and set the following properties:
  - Name: tbObjName
  - Anchors > Right:  True
  - Height: 300
  - Left: 150
  - Text: *{blank}*
  - TextHint: Object Class Name
  - Top: 150
  - Width: 2250
6. Create a text box and set the following properties:
  - Name: tbCollName
  - Anchors > Right:  True
  - Height: 300
  - Left: 150
  - Text: *{blank}*
  - TextHint: Collection Class Name
  - Top: 600
  - Width: 2250
7. Create a button and set the following properties:
  - Name: btnCreateClass
  - Anchors > Right:  True
  - Caption: Create Collection Class
  - Height: 450
  - Left: 150
  - Top: 1050
  - Width: 2250
8. Create a version label
  - Caption: Version {hhmm}

## Edit the Code in myToolWindow.twin

1. Delete the Timer1\_Timer() and HelloWorld\_Click() subroutines
2. Add a Click event handler for btnCreateClass using the code below

```
Private Sub btnCreateClass_Click()  
    MsgBox "Object class name: " & Me.tbObjName.Text & vbCrLf & _  
        "Collection class name: " & Me.tbCollName.Text, vbInformation,  
"Create Class"  
End Sub
```

## Test the Updated Addin

1. Make sure Access is closed then **Build** the tB project
2. Reopen Access and switch to VBA
3. Enter sample text `oVehicle` for object class name and `collVehicles` for collection class name then click [Create Collection Class]

## Strongly-Typed Collection Class

Now, let's talk about what this add-in will actually, you know, *do*.

The purpose of the add-in is to encapsulate the `BuildStronglyTypedCollection()` function as described here: [Strongly-Typed Collections: The Easy Way](#)

I put a link to this article in the Resources page for today's presentation. If you've never heard of strongly-typed collection classes, I recommend you read up on them later.

For our purposes, the important thing to know about them is that you CANNOT build them in the VBA editor. They require setting a couple of hidden code attributes that only appear when you export the code module to a text file.

As you can imagine, manually jumping through those hoops is inefficient and error-prone. The existing code I wrote in VBA does automate the process, but it requires importing several additional dependencies. Our VBE add-in will be a direct replacement for the `BuildStronglyTypedCollection()` function.

## Copy the VBA Code Into twinBASIC

1. Create a new module named `MyModule.twin`

## Build and Test the Addin on a Different Machine and Bitness

The following instructions assume you are building on a machine with 32-bit Office (mjw20), but installing on a machine with 64-bit Office (e.g., gbm18):

1. Ensure "**win64**" is selected in dropdown
2. **File > Build**
3. I copied `M:\Repos\NLS\DevCon2024\Build\DevCon2024_win64.dll` to `%fb%\12114\DevCon2024_win64.dll` (I will test registering it tomorrow on gbm18)
4. Open a non-admin cmd prompt
5. Run: `regsvr32 DevCon2024_win64.dll`
  - Receive message: "DllRegisterServer in DevCon2024\_win64.dll succeeded."

6. Open Word (or Excel) - The add-in appears.

## Copy and Paste Working VBA Code into twinBASIC

1. Add a standard code module named "MyModule":
  1. Right-click Sources > **Add > Add Module (.TWIN supporting Unicode)**
2. Go to [Strongly-Typed Collections: The Easy Way](#)
  1. Copy and paste the [GetGuidBasedTempPath code](#)
  2. Copy and paste the [FileWrite code](#)
3. Handle "Unrecognized datatype symbol 'Scripting'" error in DIAGNOSTICS pane:
  1. Go to **Project > References**
  2. Switch to "Available COM References" tab
  3. Search for "script" and then click the "Microsoft Scripting Runtime" reference
  4. Click [Save Changes]

## Add fafalone's WinDevLib Package for API Calls

1. **Project > References...**
2. Switch to "Available Packages" tab
3. Search for "windows"
4. Check box next to " Windows Development Library for twinBASIC vX.Y.ZZZ"
  - The package will immediately begin downloading in the background
  - When the download finishes, the name will change to " [IMPORTED] Windows Development Library for twinBASIC vX.Y.ZZZ"
  - NOTE: "[WinDevLib for Implements](#)" is a different package
5. Click [Save Changes]
6. Comment out (or delete) API `Declare` lines throughout the project
  - Be aware that if you used non-standard `Alias` names, you may need to adjust your API calls to match the standard versions used in WinDevLib
  - **myAddIn.twin:**
    - Delete Private Type RECT structure
    - Delete GetClientRect() function declare
  - **InterProcess.twin:**
    - Delete GetCurrentProcessId() function declare line...
    - ...through Type UUID structure
  - **MyModule.twin:**
    - Delete Sleep sub declare
    - Comment out CoCreateGuid function declare and highlight the failure to compile due to the stricter typing of id As UUID in WinDevLib versus id As Any in my code
    - Uncomment the CoCreateGuid function to show that explicit API declares override the WinDevLib versions
7. Pass Unicode strings directly to API declare functions
  - Most string-related API functions have ANSI and Unicode versions ("A" and "W" for "ANSI" and "Wide", respectively)
  - Lots of legacy VB6/VBA code use the ANSI version of API functions

- WinDevLib [encourages the use of Unicode versions](#) by default
- This means that code that passes input strings to API functions may require wrapping the string in ``StrPtr()`` (or removing ``StrPtr()``) from your existing code
- Remove `StrPtr()` from calls to `FindWindowEx()` in `InterProcess.callerApplicationObject`
- Convert final argument from `0&` to `vbNullString` for calls to `FindWindowEx()` in `InterProcess.callerApplicationObject`
